**Substituted imidazo-fused 6-membered heterocycles as angiotensin II antagonists.**

Substituted Imidazo-fused 6-membered heterocycles of structural formula:

wherein A, B, C, and D are independently carbon atoms or nitrogen atoms are angiotensin II antagonists useful in the treatment of hypertension and congestive heart failure.

## SUBSTITUTED IMIDAZO-FUSED 6-MEMBERED HETEROCYCLES AS ANGIOTENSIN II ANTAGONISTS

SUMMARY OF THE INVENTION

This invention relates to novel compounds of structural formula I which are angiotensin II antagonists useful in the treatment of hypertension, congestive heart failure, and elevated intraocular pressure.

It also relates to processes for preparing the novel compounds; pharmaceutical formulations comprising one or more of the compounds as active ingredient; and, a method of treatment of hypertension, congestive heart failure, and elevated intraocular pressure.

10 BACKGROUND OF THE INVENTION

Renin-angiotensin system (RAS) plays a central role in the regulation of normal blood pressure and seems to be critically involved in hypertension development and maintenance as well as congestive heart failure. Angiotensin II (All), an octapeptide hormone is produced mainly in the blood during the cleavage of angiotensin I by angiotensin converting enzyme (ACE) localized on the endothelium of blood vessels of lung, kidney, and many other organs, and is the end product of the RAS. All is a powerful arterial vasoconstrictor that exerts its action by interacting with specific receptors present on cell membranes. One of the possible modes of controlling the RAS is angiotensin II receptor antagonism. Several peptide analogs of A II are known to inhibit the effect of this hormone by competitively blocking the receptors, but their experimental and clinical applications have been limited by the partial agonist activity and lack of oral absorption [M. Antonaccio. Clin. Exp. Hypertens. A4, 27-46 (1982); D. H. P. Streeten and G. H. Anderson, Jr. - Handbook of Hypertension, Clinical Pharmacology of Antihypertensive Drugs, ed. A. E. Doyle, Vol. 5, pp. 246-271, Elsevier Science Publisher, Amsterdam, The Netherlands, 1984].

Recently, several non-peptide compounds have been described as A II antagonists. Illustrative of such compounds are those disclosed in U.S. Patents 4,207,324; 4,340,598; 4,576,958; 4,582,847; and 4,880,804; in European Patent Applications 028,834; 245,637; 253,310; and 291,969; and in articles by A.T. Chiu, et al. [Eur. J. Pharm. Exp. Therap, 157, 13-21 (1988)] and by P.C. Wong, et al. [J. Pharm. Exp. Therap, 247, 1-7 (1988)]. All of the U.S. Patents, European Patent Applications 028,834 and 253,310 and the two articles disclose substituted imidazole compounds which are generally bonded through a lower alkyl bridge to a substituted phenyl. European Patent Application 245,637 discloses derivatives of 4,5,6,7-tetrahydro-2H-imidazo[4,5-c]pyridine-6-carboxylic acid and analogs thereof as antihypertensive agents.

None of the compounds disclosed in the above identified U.S. Patents, European Applications and articles have the heterobicyclic structure of the compounds of this invention.

35 DETAILED DESCRIPTION OF THE INVENTION

This invention relates to substituted imidazo-fused 6-membered ring heterocycles of the formula I shown below which are angiotensin II antagonists and are useful in the treatment of hypertension, congestive heart failure, and elevated intraocular pressure.

The compounds of Formula (I) can be synthesized using the reactions and techniques described herein below. The reactions are performed in a solvent appropriate to the reagents and materials employed and  
 40 suitable for the transformation being effected. It is understood by those skilled in the art of organic synthesis that the functionality present on the heterocycle and in the reactants being employed should be consistent with the chemical transformations being conducted. Depending upon the reactions and techniques employed, optimal yields may require changing the order of synthetic steps or use of protecting groups followed by deprotection.

As shown in Reaction Scheme 1, compounds of Formula I can be prepared by carrying out direct alkylation of alkali-metal salts of heterocycles (1) (preparation of heterocycles are described in Reaction Schemes 3-6) using appropriately protected benzyl halide, tosylate (OTs) or mesylate (OMs) derivatives (2). The salt is prepared preferably using MH (where M is lithium, sodium or potassium) in anhydrous dimethylformamide (DMF), or by treating it with a metal alkoxide such as sodium or potassium methoxide, ethoxide or t-butoxide in an appropriate alcohol such as methanol, ethanol or t-butanol as the solvent. The alkylation is generally carried out by dissolving the metal salt of the heterocycle in a dipolar aprotic solvent such as DMF or dimethylsulfoxide (DMSO) and reacting it with the alkylating agent at 20° C to reflux temperature of the solvent for 1-24 hours.

## REACTION SCHEME 1

where Q = halo(I, Br, Cl), -O-tosyl, -O-mesyl

50 If substituents and/or the hetero atom positions in the six-membered ring are not symmetrically disposed, the alkylation on the imidazole nitrogen(s) generally produces a mixture of two regioisomers as products arising from N<sup>1</sup> and N<sup>3</sup> alkylation. These regioisomers I and Ia possess distinct physico-chemical and biological properties and in most cases can be separated and purified by using conventional separation techniques such as chromatography (flash column chromatography, medium-pressure liquid chromatog-

55 raphy, high performance liquid chromatography) and/or crystallization. In those cases where separation of regioisomers is difficult by conventional techniques, the mixture can be transformed into suitable derivatives that can be separated by the above separation methods. The structural assignments of the isomers can be made using Nuclear Overhauser Effect (NOE), <sup>1</sup>H-<sup>13</sup>C coupled NMR experiments or X-ray crystallography.

When there is potential for alkylation in the 6-membered heterocyclic ring, this can be avoided by the use of suitable protecting groups.

The substituted benzyl halides (2) including the more preferred alkylating agents (8a and 8b and 8c, Reaction Scheme 2) can be prepared as described in European Patent Applications 253,310 and 291,969 and the references cited therein. In addition a preferred method to prepare the biphenyl precursors 7a, 7b using Ni(0) or Pd(0) catalyzed cross-coupling reaction [E. Negishi, T. Takahashi, and A. O. King, *Org. Synthesis*, 66, 67 (1987)] is outlined in Reaction Scheme 2. As shown in Reaction Scheme 2, treatment of 4-bromotoluene (3) with t-BuLi, followed by the addition of a solution of ZnCl<sub>2</sub>, produces the organo-zinc compound (5). Compound (5) is then coupled with 6a or 6b in the presence of Ni(PPh<sub>3</sub>)Cl<sub>2</sub> catalyst to produce the desired biphenyl compound 7a or 7b. Similarly, 1-bromo-2-nitrobenzene (6c) is coupled with organo-zinc compound 5 in the presence of Pd(PPh<sub>3</sub>)<sub>4</sub> catalyst [prepared by treating Cl<sub>2</sub>Pd(PPh<sub>3</sub>)<sub>2</sub> with (i-Bu)<sub>2</sub>AlH (2 equiv.)] to give the biphenyl compound 7c. These precursors, 7a, 7b and 7c, are then transformed into halomethylbiphenyl derivatives 8a, 8b and 8c, respectively, according to procedures described in European Patent Applications 253,310 and 291,969.

When there is additional substitution on the second phenyl ring (R<sup>2</sup> not hydrogen) the preferred method to prepare the biphenyl precursors 7d and 7e, using the Pd(0) catalyzed cross-coupling reaction [J. K. Stille, *Angew. Chem. Int. Ed. Engl.*, 25, 508 (1986)], is outlined in reaction Scheme 2a. As shown in reaction Scheme 2a, p-tolyltrimethyltin (5a) is coupled with 6d or 6e in refluxing toluene in the presence of 5 mole % of Pd(PPh<sub>3</sub>)<sub>4</sub> to produce the desired biphenyl compounds 7d and 7e. Table I illustrates the synthetic utility of this protocol. Compounds 7d (R<sup>2</sup> = NO<sub>2</sub>) and 7e (R<sup>2</sup> = NO<sub>2</sub>) could be converted to their respective chlorides by catalytic hydrogenation, diazotization and treatment with copper (I) chloride. The biphenyl fluorides which could not be obtained by direct coupling to a fluoro arylbromide were prepared from 7d (R<sup>2</sup> = NO<sub>2</sub>) and 7e (R<sup>2</sup> = NO<sub>2</sub>) via reduction, formation of the diazonium tetrafluoroborate salt and thermal decomposition. These precursors 7d (R<sup>2</sup> = NO<sub>2</sub> or F or Cl) and 7e (R<sup>2</sup> = NO<sub>2</sub> or F or Cl) are then transformed into the halomethyl biphenyl derivatives 8d and 8e, respectively according to the procedures described in European Patent Applications 253,310 and 292,969.

The heterocycles of type (1) can be prepared by any of the standard procedures described in the literature [J.A. Montgomery and J.A. Secrist III in "Comprehensive Heterocyclic Chemistry," Vol. 5, A.R. Katritzky and C.W. Rees Eds., Pergamon Press 1984; pp 567-597 and 631-656 and references cited therein]. As shown in Reaction Scheme 3, the most widely used starting materials are six member heterocyclic vicinal diamines (9). Fused imidazoles (10) can be prepared by condensation of (9) with an appropriate carboxylic acid, nitrile, imidate ester, or orthoesters, either neat, or in a solvent appropriate and

compatible with the starting materials and reagents, such as polyphosphoric acid, ethanol, methanol, hydrocarbon solvents, and with a catalytic amount of acid if required. Oxidation of an imine formed by reaction of diamine (9) with an appropriate aldehyde using oxidants such as Cu (II), nitrobenzene, or 2,3-dichloro-5,6-dicyano-1,4-benzoquinone (DDQ) also affords heterocycles (10). Aminoamides (11, W = H) or diamides (11, W = R<sup>6</sup>CO) can be converted to fused imidazoles (10) by heating neat, or at an elevated temperature in a solvent such as xylene under acidic or neutral conditions.

As shown in Reaction Scheme 4, methods of preparing heterocycles of types (12 and 13) involve treatment of diamines (9) with reagents such as urea, phosgene, potassium cyanate, alkyl chloroformates, dialkylcarbonate, or carbon disulfide in the presence of bases such as potassium hydroxide or potassium carbonate. Amino acids (14) or (15) can be converted to (13) via Curtius or Hoffman rearrangement on suitable derivatives such as acyl azides, hydroxy amides, or N-haloamides. Bicyclic compounds of type (16, E = sulfur or oxygen) are formed from 12 by reaction under neutral or basic conditions with alkyl halides, alkylmesylates, alkyltosylates, trialkyloxonium salts, or with an appropriate diazoalkane. Compounds of type (16; E = oxygen or sulfur) are prepared by displacement reactions using alkoxides or alkyl mecaptides with chloro intermediates as indicated.

Diamines of type 9 can be prepared by a wide variety of methods such as hydrolysis of bis-amides or amino amides, reduction of dinitro or aminonitro or hydrazino or azido groups, displacement of heteroaromatic halides or alkoxy or thio or alkylthio or hydroxy or alkyl sulfonyl groups with ammonia or amines, or rearrangement of acyl azides or amides or acids (Curtius, Hofman, or Schmidt rearrangements). [A.S. Tomcufcik, L.N. Starker in "Heterocyclic Compounds, Pyridine and it's Derivatives" Pt 3, E. Klingsberg Ed., Wiley Interscience, 1962, pp 59-62, and references cited there in; T. Nakagome in "Heterocyclic Compounds, Pyridazines" Vol. 28, R.N. Castle, Ed., Wiley Interscience, 1973, pp 597-601, and references cited therein; "Heterocyclic Compounds, The Pyrimidines" Vol. 16, D.J. Brown Ed., Wiley Interscience 1985, pp 299-325; E. Schipper, and A.R. Day J. Am. Chem. Soc. (1952) 74, 350; "Comprehensive Heterocyclic Chemistry," Vol. 5, A.R. Katritzky and C.W. Rees Eds., Pergamon Press 1984; pp 567-597 and 631-656 and references cited therein].

In cases wherein heterocycles of type 10 or 16 are not easily prepared from their corresponding diamines, or when these diamines cannot be prepared then alternative routes, involving fusion of the six member heterocycle onto an appropriately substituted imidazole, are used. Two of these routes are illustrated in Reaction Scheme 5. For example, imidazo[4,5-d][1,2,3]triazines (18) are preferentially prepared by treatment of amino carboxamido imidazoles (17) with sodium nitrite in aqueous acid. Precursor imidazoles (17) are prepared by degradation of an appropriately substituted xanthine or by condensation of an appropriate imidate ester with aminocynoacetamide. Imidazo[4,5-b]pyridazines (20) can be prepared from imidazodicarboxylate esters (19) by treatment with hydrazine. Oxidation of (20) gives pyridazindiones (21). The oxygen(s) in (20) or (21) can be converted to other functionalities such as halides or thiones, which are themselves precursors for the synthesis of more elaborate systems ["Comprehensive Heterocyclic Chemistry," Vol. 5, A.R. Katritzky and C.W. Rees Eds., Pergamon Press 1984; pp 567-597 and 631-656 and references cited therein].

## REACTION SCHEME 5

Moreover, as shown in Reaction Scheme 6, amino imidazole esters and amides are versatile intermediates for the preparation of purines. This scheme also illustrates the synthesis of the 6-membered heterocyclic ring after the alkylating agent 2 has been reacted with a suitably substituted imidazole to afford 22 or 24.

## REACTION SCHEME 6

The preparation of reduced forms of heterocycles can be achieved by catalytic reduction, or by synthesis from a suitable imidazole precursor. For example, histidine and derivatives thereof react with formaldehyde to afford partially saturated imidazo(4,5-c) pyridines [cf. Neuberger, A. Biochem. J., (1944), 38, 309].

Compounds of formula I where  $R^1$  is  $-COHNSO_2R^{23}$  (where  $R^{23}$  = alkyl, aryl or heteroaryl) may be prepared from the corresponding carboxylic acid derivatives (I) as outlined in Scheme 7. The carboxylic acid (I), obtained as described in Scheme 1, can be converted into the corresponding acid chloride by treatment with refluxing thionyl chloride or preferably with oxalylchloride and a catalytic amount of dimethylformamide at low temperature [A. W. Burgstahler, L. O. Weigel, and C. G. Shaefer -Synthesis, 767, (1976)]. The acid chloride then can be treated with the alkali metal salt of  $R^{23}SO_2NH_2$  to form the desired acylsulfonamide 26. Alternatively, these acylsulfonamides may be also prepared from the carboxylic acids using N,N-diphenylcarbamoyl anhydride intermediates [F. J. Brown et al - European Patent Application, EP 199543; K. L. Shepard and W. Halczenko - J. Het. Chem., 16, 321 (1979)]. Preferably the carboxylic acids can be converted into acyl-imidazole intermediates, which then can be treated with an appropriate aryl or alkylsulfonamide and diazabicycloundecane (DBU) to give the desired acylsulfonamide 26 [J. T. Drummond and G. Johnson -Tetra. Lett., 29, 1653 (1988)].

- c) (i) N(N-Diphenylcarbonyl)pyridinium chloride/Aq. NaOH  
 (ii)  $R^{23}SO_2NH-M^+$ .

Compounds of formula I where  $R^1$  is  $-SO_2NHCOR^{23}$  may be prepared as outlined in Scheme 8. The nitro compound 7c (prepared as described in Scheme 2) can be reduced to the corresponding amino compound and converted into aromatic diazonium chloride salt, which then can be reacted with sulfur dioxide in the presence of a copper(II) salt to form the corresponding arylsulfonylchloride 27 [H. Meerwein, G. Dittmar, R. Gollner, K. Hafner, F. Mensch and O. Steifort - Chem. Ber., 90, 841 (1957); A. J. Prinsen and H. Cerfontain, Recueil, 84, 24 (1965); E. E. Gilbert, Synthesis, 3 (1969) and references cited therein]. The sulfonyl chloride can be reacted with ammonia in aqueous solution or in an inert organic solvent [F. H.

Bergheim and W. Baker, J. Amer. Chem. Soc., 66, (1944), 1459], or with dry powdered ammonium carbonate, [E. H. Huntress and J. S. Autenrieth, J. Amer. Chem. Soc., 63, (1941), 3446; E. H. Huntress and F. H. Carten, J. Amer. Chem. Soc., 62, (194), 511] to form the sulfonamide 28. The benzylbromide 30 may be prepared from the sulfonamide 28 as outlined in Scheme 8, and then can be reacted with an alkali metal salt of an appropriate heterocyclic compound to form the key sulfonamide 31. The sulfonamide 31 may be also prepared from the aromatic sulfonyl chloride 36, which may be prepared from the aryl amine 35 as outlined in Scheme 9. The acylation of 31 with appropriate acyl chlorides (or acyl-imidazoles or other acylating agents) may produce the desired acylsulfonamides 32.

The compounds bearing  $R^1$  as  $-SO_2NHR^{23}$  (where  $R^{23}$  is heteroaryl) may be prepared by reacting the aromatic sulfonyl chloride 36 with appropriate heteroaryl amines as outlined in Scheme 9. The sulfonyl chloride 36 may be the preferred intermediate for the synthesis of this class of compounds. The aromatic sulfonyl chlorides may also be prepared by reacting the sodium salt of aromatic sulfonic acids with  $PCl_5$  or  $POCl_3$  [C. M. Suter, The organic Chemistry of Sulfur, John Wiley & sons, 459, (1944)]. The aromatic

sulfonic acid precursors may be prepared by chlorosulfonation of the aromatic ring with chlorosulfonic acid [E. H. Huntress and F. H. Carten, *J. Amer. Chem. Soc.*, **62**, 511 (1940)].

The biaryl sulfonamides **28a** and **29** can be prepared alternatively using palladium(0) catalyzed cross-coupling reactions of appropriate aryl-organotin precursors [J. K. Stille, *Pure Appl. Chem.*, **57**, 1771 (1985); T. R. Baiely, *Tetra Lett.*, **27**, 4407 (1986); D. A. Widdowson and Y. Z. Zhang, *Tetrahedron*, **42**, 2111 (1986)], as outlined in Scheme 10. The organotin compound **39** [S. M. Moerlein, *J. Organometallic Chem.*, **319**, 29 (1987)], obtained from the aromatic precursor **38**, may be coupled with aryl sulfonamides **41** and **42** using Pd(PPh<sub>3</sub>)<sub>4</sub> or (PPh<sub>3</sub>)<sub>2</sub>PdCl<sub>2</sub> as catalysts to give biaryl sulfonamides **28a** and **29**, respectively. Similarly, the benzyl bromide **30** may be alternatively prepared from the appropriate organotin precursor **45** using the Pd(0) catalyzed cross-coupling reaction as outlined in Scheme 11.

The compounds bearing  $R^1$  as  $-\text{CH}_2\text{SO}_2\text{NHCOR}^{23}$  and  $-\text{CH}_2\text{SO}_2\text{NHR}^{23}$  may be prepared as outlined in Scheme 12. The key precursor aryl-methanesulfonyl chloride 52 may be prepared either from the reaction of aryl-methylmagnesium chloride (51) (obtained from the corresponding benzyl chloride (48)) with sulfonyl-chloride [S. N. Bhattacharya, C. Eaborn and D. P. M. Walton, *J. Chem. Soc. C*, 1265 (1968)], or by oxidation of the aryl-methylthioacetate (50) (prepared from the benzyl bromide 49) with chlorine in presence of trace amount of water [Bagnay and Dransch, *Chem. Ber.*, 93, 784 (1960)]. Alternatively, the aryl-methylthioacetate (50) may be oxidized with sulfonyl chloride in presence of acetic anhydride to form aryl-methylsulfinyl chloride [S. Thea and G. Cevasco, *Tetra. Lett.*, 28, 5193 (1987)], which can be further oxidized with appropriate oxidizing agents to give the sulfonyl chloride 52. The compounds 53 and 54 can be obtained by reacting the sulfonyl chloride 52 with appropriate amines.

Compounds where  $R^1 = -\text{NHSO}_2\text{NHR}^{23}$  may be prepared by the reaction of appropriate primary amines with the sulfamide 56 [S. D. McDermott and W. J. Spillane, *Synthesis*, 192 (1983)], as described in Scheme 13. The compound 56 may be obtained from the corresponding N-t-butylsulfamide 55 after treatment with anhydrous trifluoroacetic acid [J. D. Catt and W. L. Matier, *J. Org. Chem.*, 39, 566 (1974)], which may be prepared by the reaction of the aromatic amine 35 with t-butylsulfamoyl chloride [W. L. Matier, W. T. Comer and D. Deitchman, *J. Med. Chem.*, 15, 538 (1972)].

Antagonists of Formula I in which  $R^1 = -\text{NHSO}_2\text{CF}_3$  may be prepared as illustrated in Schemes 9 and 14. Bromination of 7c (prepared as described in Scheme 2) with N-bromosuccinimide affords 4-bromomethyl-2'-nitrobiphenyl (33). This bromide is then used to alkylate the sodium salt of an appropriate heterocyclic compound in anhydrous DMF, affording 34. Subjection of 34 to catalytic reduction with Pd/C catalyst then affords the corresponding amino-derivative 35, which is converted upon treatment with trifluoromethanesulfonic anhydride to the sulfonamide 58.

Antagonists of Formula I in which  $R^1 = -\text{CH}_2\text{SO}_2\text{NHCOR}^{23}$  may be prepared as illustrated in Scheme 15. 2-Bromotoluene (59) is treated with t-butyllithium and then zinc chloride. Coupling of the resulting metallo-zinc species with 4-bromobenzoic acid methyl ester (60) is then carried out with bis-(triphenylphosphine)nickel(II) chloride as catalyst. Bromination of the resulting biphenyl (61) is then carried out using N-bromosuccinimide, affording bromide 62. Treatment of the bromide with thiourea affords the salt 63 which is treated with chlorine to yield sulfonyl chloride 64. Treatment of 64 with t-butylamine affords sulfonamide 65, which is converted by treatment with lithium aluminum hydride to the alcohol 66. Conversion of 66 to the corresponding iodide 67 is carried out by treatment with methanesulfonyl chloride to afford a sulfonate ester, followed by treatment with sodium iodide in acetone. The iodide 67 is used to alkylate the sodium salt of an appropriate heterocyclic compound, affording the sulfonamide 68. Treatment of 68 with trifluoroacetic acid then affords the sulfonamide analog 69, which on further treatment with acetic anhydride and pyridine affords the desired acylsulfonamides 70.

Halogenation of the imidazo[4,5-b]pyridine ring at the 6-position can be accomplished using  $\text{Br}_2$ , or N-bromosuccinimide. Halogenation of the 7-position can be accomplished by reaction of the corresponding imidazopyridine-4-oxide (prepared by reaction of the imidazopyridine with peracids such as m-chloroperoxybenzoic acid) with  $\text{POCl}_3$ . When the 7-position is substituted with other than hydrogen, halogenation at the 5-position of the 4(N)-oxide precursor occurs upon treatment with  $\text{POCl}_3$ . Chlorides may be substituted by bromides or iodides by treatment with either HBr or HI, respectively, in a solvent such as HOAc.

2-Alkyl-imidazo[4,5-b]pyridines can be substituted at the 5, 6, or 7 positions by displacement of a halogen at that position by nucleophiles such as cyanide, amines, copper alkoxides, trialkylphosphites, and thiolates. Also, substitution of the halogens, in particular bromides or iodides, can be accomplished by reaction with a coupling partner such as alkylzinc or arylzinc halides, or monoalkylarylphosphonites in the presence of an appropriate metal catalyst such as nickel, palladium, ruthenium, or platinum. In cases where the reaction is sluggish or complicated due to an acidic proton, the imidazopyridine may be protected at the 1, 3, or 4 positions by benzyl or other arylmethyl groups.

It will be appreciated by those skilled in the art that functional group transformations can be conducted on aryl and heterocyclic rings to afford desired analogs. For example, esters may be converted to amides by heating them with amines and an amide nitrogen if present in the heterocycle may be alkylated using bases such as sodium hydride in DMF with the appropriate alkyl halide. Functional group protection throughout these syntheses will be chosen to be compatible with subsequent reaction conditions. Ultimately such protecting groups will be removed to generate the desired optimally active compounds of Formula I. For example,  $R^1$  as carboxyl is often protected as its t-butyl ester which in the last step is removed by treatment with trifluoroacetic acid. Aqueous acetic acid at room temperature overnight is a preferred method to remove a trityl protecting group to liberate an  $R^1$  tetrazole group.

The compounds of this invention form salts with various inorganic and organic acids and bases which are also within the scope of the invention. Such salts include ammonium salts, alkali metal salts like sodium

and potassium salts, alkaline earth metal salts like the calcium and magnesium salts, salts with organic bases; e.g., dicyclohexylamine salts, N-methyl-D-glucamine, salts with amino acids like arginine, lysine, and the like. Also, salts with organic and inorganic acids may be prepared; e.g., HCl, HBr, H<sub>2</sub>SO<sub>4</sub>, H<sub>3</sub>PO<sub>4</sub>, methane-sulfonic, toluene-sulfonic, maleic, fumaric, camphorsulfonic. The non-toxic, physiologically, acceptable salts are preferred, although other salts are also useful; e.g., in isolating or purifying the product.

The salts can be formed by conventional means such as by reacting the free acid or free base forms of the product with one or more equivalents of the appropriate base or acid in a solvent or medium in which the salt is insoluble, or in a solvent such as water which is then removed in vacuo or by freeze-drying or by exchanging the cations of an existing salt for another cation on a suitable ion exchange resin.

Angiotensin II (All) is a powerful arterial vasoconstrictor, and it exerts its action by interacting with specific receptors present on cell membranes. The compounds described in the present invention act as competitive antagonists of All at the receptors. In order to identify All antagonists and determine their efficacy in vitro, the following two ligand-receptor binding assays were established.

#### Receptor binding assay using rabbit aortae membrane preparation:

Three frozen rabbit aortae (obtained from Pel-Freeze Biologicals) were suspended in 5mM Tris-0.25M Sucrose, pH 7.4 buffer (50 ml) homogenized, and then centrifuged. The mixture was filtered through a cheesecloth and the supernatant was centrifuged for 30 minutes at 20,000 rpm at 4° C. The pellet thus obtained was resuspended in 30 ml of 50mM Tris-5 mM MgCl<sub>2</sub> buffer containing 0.2% Bovine Serum Albumin and 0.2 mg/ml Bacitracin and the suspension was used for 100 assay tubes. Samples tested for screening were done in duplicate. To the membrane preparation (0.25 ml) there was added <sup>125</sup>I-Sar<sup>1</sup>Ile<sup>8</sup>-angiotensin II [obtained from New England Nuclear] (10ul; 20,000 cpm) with or without the test sample and the mixture was incubated at 37° C for 90 minutes. The mixture was then diluted with ice-cold 50mM Tris-0.9% NaCl, pH 7.4 (4ml) and filtered through a glass fiber filter (GF/B Whatman 2.4" diameter). The filter was soaked in scintillation cocktail (10 ml) and counted for radioactivity using Packard 2660 Tricarb liquid scintillation counter. The inhibitory concentration (IC<sub>50</sub>) of potential All antagonist which gives 50% displacement of the total specifically bound <sup>125</sup>I-Sar<sup>1</sup>Ile<sup>8</sup>-angiotensin II was presented as a measure of the efficacy of such compounds as All antagonists.

#### Receptor assay using Bovine adrenal cortex preparation

Bovine adrenal cortex was selected as the source of All receptor. Weighed tissue (0.1 g is needed for 100 assay tubes) was suspended in Tris.HCl (50mM), pH 7.7 buffer and homogenized. The homogenate was centrifuged at 20,000 rpm for 15 minutes. Supernatant was discarded and pellets resuspended in buffer [Na<sub>2</sub>HPO<sub>4</sub> (10mM)-NaCl (120mM)-disodium EDTA (5mM) containing phenylmethane sulfonyl fluoride (PMSF)(0.1mM)]. (For screening of compounds, generally duplicates of tubes are used). To the membrane preparation (0.5 ml) there was added 3H-angiotensin II (50mM) (10ul) with or without the test sample and the mixture was incubated at 37° C for 1 hour. The mixture was then diluted with Tris buffer (4ml) and filtered through a glass fiber filter (GF/B Whatman 2.4" diameter). The filter was soaked in scintillation cocktail (10ml) and counted for radioactivity using Packard 2660 Tricarb liquid scintillation counter. The inhibitory concentration (IC<sub>50</sub>) of potential All antagonist which gives 50% displacement of the total specifically bound <sup>3</sup>H-angiotensin II was presented as a measure of the efficacy of such compounds as All antagonists.

The antihypertensive effects of the compounds described in the present invention may be evaluated using the methodology described below:

Male Charles River Sprague-Dawley rats (300-375 gm) were anesthetized with methohexital (Brevital; 50 mg/kg i.p.) and the trachea was cannulated with PE 205 tubing. A stainless steel pithing rod (1.5 mm thick, 150 mm long) was inserted into the orbit of the right eye and down the spinal column. The rats were immediately placed on a Harvard Rodent Ventilator (rate - 60 strokes per minute, volume -1.1 cc per 100 grams body weight). The right carotid artery was ligated, both left and right vagal nerves were cut, and the left carotid artery was cannulated with PE 50 tubing for drug administration, and body temperature was maintained at 37° C by a thermostatically controlled heating pad which received input from a rectal temperature probe. Atropine (1 mg/kg i.v.) was then administered, and 15 minutes later propranolol (1 mg/kg i.v.). Thirty minutes later angiotensin II or other agonists were administered intravenously at 30-minute intervals and the increase in the diastolic blood pressure was recorded before and after drug or

vehicle administration.

Using the methodology described above, representative compounds of this invention were evaluated and were found to exhibit an activity of at least  $IC_{50} < 50 \mu M$ , thereby demonstrating and confirming the utility of the compounds of the invention as effective A II antagonists.

5 The compounds of the invention are useful in treating hypertension. They are also of value in the management of acute and chronic congestive heart failure. These compounds may also be expected to be useful in the treatment of secondary hyperaldosteronism, primary and secondary pulmonary hyperaldosteronism, primary and secondary pulmonary hypertension, renal failure such as diabetic nephropathy, glomerulonephritis, scleroderma, glomerular sclerosis, proteinuria of primary renal disease, end stage renal  
10 disease, renal transplant therapy, and the like, renal vascular hypertension, left ventricular dysfunction, diabetic retinopathy and in the management of vascular disorders such as migraine, Raynaud's disease, luminal hyperclasia, and to minimize the atherosclerotic process. The application of the compounds of this invention for these and similar disorders will be apparent to those skilled in the art.

The compounds of this invention are also useful to treat elevated intraocular pressure and to enhance  
15 retinal blood flow and can be administered to patients in need of such treatment with typical pharmaceutical formulations such as tablets, capsules, injectables and the like as well as topical ocular formulations in the form of solutions, ointments, inserts, gels, and the like. The compounds of this invention can be administered to patients (animals and human) in need of such treatment in dosages that will provide optimal pharmaceutical efficacy. Although the  
25 dose will vary from patient to patient depending upon the nature and severity of disease, the patient's weight, special diets then being followed by a patient, concurrent medication, and other factors which those skilled in the art will recognize, the dosage range will generally be about 1 to 1000 mg. per patient per day which can be administered in single or multiple doses. Preferably, the dosage range will be about 2.5 to 250 mg. per patient per day; more preferably about 5 to 150 mg. per patient per day.

45 are given singly.

To illustrate these combinations, one of the angiotensin II antagonists of this invention effective clinically in the 2.5-250 milligrams per day range can be effectively combined at levels at the 0.5-250 milligrams per day range with the following compounds at the indicated per day dose range: hydrochlorothiazide (15-200 mg) chlorothiazide (125-2000 mg), ethacrynic acid (15-200 mg), amiloride (5-20 mg), furosemide (5-80 mg),

In addition, triple drug combinations of hydrochlorothiazide (15-200 mg) plus amiloride (5-20 mg) plus angiotensin II antagonist of this invention (3-200 mg) or hydrochlorothiazide (15-200 mg) plus timolol maleate (5-60) plus an angiotensin II antagonist of this invention (0.5-250 mg) or hydrochlorothiazide (15-200 mg) and nifedipine (5-60 mg) plus an angiotensin II

Naturally, these dose ranges can be adjusted on a unit basis as necessary to permit divided daily dosage and, as noted above, the dose will vary depending on the nature and severity of the disease, weight of patient, special diets and other factors.

Typically, these combinations can be formulated into pharmaceutical compositions as discussed below.

About 1 to 100 mg. of compound or mixture of compounds of Formula I or a physiologically acceptable salt is compounded with a physiologically acceptable vehicle, carrier, excipient, binder, preservative, stabilizer, flavor, etc., in a unit dosage form as called for by accepted pharmaceutical practice. The amount of active substance in these compositions or preparations is such that a suitable dosage in the range indicated is obtained.

Illustrative of the adjuvants which can be incorporated in tablets, capsules and the like are the following: a binder such as gum tragacanth, acacia, corn starch or gelatin; an excipient such as microcrystalline cellulose; a disintegrating agent such as corn starch, pregelatinized starch, alginic acid and the like; a lubricant such as magnesium stearate; a sweetening agent such as sucrose, lactose or saccharin; a flavoring agent such as peppermint, oil of wintergreen or cherry. When the unit dosage unitform is a capsule, it may contain, in addition to materials of the above type, a liquid carrier such as fatty oil. Various other materials may be present as coatings or to otherwise modify the physical form of the dosage unit. For instance, tablets may be coated with shellac, sugar or both. A syrup or elixir may contain the active compound, sucrose as a sweetening agent, methyl and propyl parabens as preservatives, a dye and a flavoring such as cherry or orange flavor.

Sterile compositions for injection can be formulated according to conventional pharmaceutical practice by dissolving or suspending the active substance in a vehicle such as water for injection, a naturally occurring vegetable oil like sesame oil, coconut oil, peanut oil, cottonseed oil, etc., or a synthetic fatty vehicle like ethyl oleate or the like. Buffers, preservatives, antioxidants and the like can be incorporated as required.

The following examples further illustrate the preparation of the compounds of Formula I and their incorporation into pharmaceutical compositions and, as such, are not to be considered or construed as limiting the invention recited in the appended claims.

The bath was then removed and the mixture was stirred at room temperature for an additional 2 hours. The content of the flask was then added slowly (using a cannula) at room temperature to a premixed solution of  $\text{ZnCl}_2$  in ether (1 M) (180 ml) and dry THF (360 ml). The mixture was stirred for 2 hours at that temperature and the slurry was added (using a cannula) to a solution of 2-t-butoxycarbonyl-iodobenzene (35.6 g), and  $\text{NiCl}_2(\text{Ph}_3\text{P})_2$  (2.1 g) in dry THF (360 ml). To a stirred suspension of NaH (104 mg of an 80% dispersion, 3.45 mmol) in dry dimethylformamide (8 mL) at room temperature was added 2-butylimidazo[4,5-b]pyridine (504 mg, 2.88 mmol). After 30 minutes, tert-butyl-4'-bromomethylbiphenyl-2-carboxylate (1.0 g, 2.88 mmol) was added in one portion. After 15

The pale yellow residue was chromatographed on silica gel, eluting with ethyl acetate. In this manner, 2.16 g (9.14 mmol, 52%) of the title compound was obtained as a fluffy, white solid. NMR (300 MHz, DMSO-d<sub>6</sub>): 0.89 (t, 3H), 1.30 (m, 2H), 1.66 (m, 2H), 2.68 (t, 2H), 3.23 (s, 3H), 3.42 (s, 3H). FAB-MS: 237 (M + H, 100%).

The organic layer was separated, dried (MgSO<sub>4</sub>), filtered and solvents removed in vacuo. The residue was purified by medium pressure liquid chromatography on silica gel, eluting with ethyl acetate/hexane (2:1), to afford 246 mg (0.35 mmol, 82%) of the trityl intermediate as a white solid. NMR (300 MHz, CDCl<sub>3</sub>): 0.87 (t, 3H), 1.30 (m, 2H), 1.61 (m, 2H), 2.57 (t, 2H), 3.37 (s, 3H), 3.58 (s, 3H), 5.43 (s, 2H), 6.8-7.8 (several multiplets, 23 H). FAB-MS: 712 (M + H, 1%), 471 (M-trityl, 7%), 243 (trityl, 100%).

Preparation of 5,7-Dimethyl-2-ethyl-3-(2'-(tetrazol-5-yl)biphen-4-yl)methyl-3H-imidazo[4,5-b]pyridine

40

Step 1: 2-Amino-4,6-dimethyl-3-nitropyridine

2-Amino-4,6-dimethylpyridine (10.0 g, 81.8 mmol) was added portion-wise to 65 mL of H<sub>2</sub>SO<sub>4</sub> (conc. d=1.84) which was stirred (mechanical) at 0 °C. After complete addition, the mixture was warmed to room temperature until the mixture became homogeneous. The solution was then cooled to -10 °C and a pre-cooled (0 °C) mixture of concentrated HNO<sub>3</sub> (11.5 mL, d = 1.40) and H<sub>2</sub>SO<sub>4</sub> (8.2 mL, d = 1.84) was added at such a rate as not to raise the internal reaction temperature above -9 °C. Ten minutes after the addition was complete this cooled (-10 °C) mixture was poured onto 400 g of crushed ice. The resulting slurry was neutralized by the addition of conc NH<sub>4</sub>OH (to pH 5.5) while cooling (ice bath). The solid was isolated by filtration, and dried at room temperature to give 13.3g of 2-nitramino-4,6-dimethylpyridine as a white solid.

50

To 75 mL of stirred conc H<sub>2</sub>SO<sub>4</sub> cooled to -5 °C (ice-salt bath) was added 4,6-dimethyl-2-nitraminopyridine (13.2 g, 79 mmol) portion-wise at such a rate as to maintain the internal temperature below -3 °C. The mixture was warmed to 0 °C until homogeneous (30 minutes) at which time tlc (SiO<sub>2</sub>, 1:1 EtOAc/hexanes on a NN<sub>4</sub>OH neutralized aliquot) indicated that the rearrangement was complete. The mixture was poured onto 400 g of crushed ice and the pH was adjusted to 5.5 by the addition of concentrated NH<sub>4</sub>OH. The resulting yellow slurry was cooled to 0 °C, filtered, washed with cold water (50 mL), and dried at room temperature to give 10.32 g of a mixture of the title compound and the 5-nitro isomer in a 55:45 ratio (determined by <sup>1</sup>H NMR). This mixture was used directly in Step 2.

55

Step 2: 5,7-Dimethyl-2-ethylimidazo[4,5-b]pyridine

The reaction vessel was evacuated then purged with N<sub>2</sub> at 1 atm. and stirred vigorously for 18 hours. Filtration (celite), and concentration gave 6.65g of a mixture of 2,3-diamino-4,6-dimethylpyridine and 2,5-diamino-4,6-dimethylpyridine as a dark solid. To 5.40g (39.4 mmol) of this mixture was added propionic acid (8.80 mL, 118 mmol) followed by polyphosphoric acid (100 mL). This stirred mixture was heated to 90 °C for 3 hours then to 100 °C for 1 hour. After the reaction was complete, the warm mixture was poured onto 300g of ice and the mixture was made basic with NH<sub>4</sub>OH. The mixture was extracted (4 x 50 mL CH<sub>2</sub>Cl<sub>2</sub>), dried (K<sub>2</sub>CO<sub>3</sub>) and concentrated to give a mixture of the title compound and 4,6-dimethyl-2,5-bis(propionamido)pyridine. Purification (SiO<sub>2</sub>, 5% MeOH/ EtOAc) gave 1.66 g of the title compound as the slower eluting component. <sup>1</sup>H NMR (CD<sub>3</sub>OD, 300MHz) δ 6.95 (s, 1H), 2.92 (q, 2H, J=7.8 Hz), 2.54 (apparent s, 6H), 1.40 (t, 3H, J=7.8 Hz)
